Environmental education in its infancy at Lake Alaotra, Madagascar

Lena M. Reibelt\textsuperscript{I,II}, Torsten Richter\textsuperscript{III}, Patrick O. Waebel\textsuperscript{I,IV}, Sandanionja Rakotoarimanana\textsuperscript{V}, Jasmin Mantilla-Contreras\textsuperscript{I}

ABSTRACT
Madagascar is renowned for its unique biodiversity but also for the continuous degradation of its natural environment and its high poverty rate. In order to achieve sustainable development, environmental education has been assigned a key role. In the lake Alaotra region, Madagascar’s most important rice and inland fish production area, primary schools are the sole formal education for the majority of the population. In order to gain an overview on the education of ‘tomorrow’s’ resource users, this study assessed the general state of the school system and of environmental education in particular. The focus was on understanding local definitions of environmental education, its application and local perceptions of environmental problems. Over 50 in-depth interviews were conducted using the Funnel approach with teachers from 18 public primary schools. The interviews were supplemented with focus groups and a participatory problem analysis workshop. Teachers in the Alaotra region provided a different definition of environmental education than the United Nations. Their focus is on social aspects rather than the actual problems of the natural environment, which represents a different point of view than non-governmental organizations (NGOs) from abroad, who are the main promoters of environmental education in the area. This indicates that education for sustainable development might be more suitable in the region than the currently promoted environmental education. When developing educational programs, it is important to include the teachers in the development processes to ensure inclusion of local views and needs. This will increase the probability that such programs are locally meaningful and useful.

RÉSUMÉ
Si Madagascar est réputée pour sa biodiversité unique, elle l’est aussi pour la dégradation de son environnement naturel et son taux de pauvreté élevé. L’éducation à l’environnement est un élément important dans l’accès au développement durable. Dans la région Alaotra qui est le principal producteur de riz et de poissons d’eau douce de Madagascar, l’éducation est dispensée presqu’exclusivement par les écoles primaires pour la majorité de la population limitrophe du lac Alaotra. Pour comprendre globalement l’éducation des futurs utilisateurs des ressources, l’étude a évalué la situation qui prévaut dans le système scolaire en général et celui de l’éducation environnementale en particulier. Les travaux se sont concentrés sur les définitions locales de l’éducation environnementale, sa mise en œuvre et les perceptions locales des problèmes environnementaux. Plus de 50 interviews détaillées ont été réalisées avec des enseignants de 18 écoles primaires sous méthode Funnel. Les interviews ont été complétées par des groupes de discussion et un atelier participatif portant sur l’analyse du problème. Les enseignants de la région de l’Alaotra ont énoncé une définition différente de l’éducation environnementale que celle proposée par les Nations Unies. Leur priorité porte davantage sur les aspects sociaux que sur les problèmes de l’environnement naturel lui-même, divergeant ainsi du point de vue des organisations non gouvernementales (ONG) étrangères, qui sont actuellement les principaux promoteurs de l’éducation environnementale dans la région. Il apparaît ainsi que l’éducation portant sur le développement durable pourrait être plus appropriée que l’éducation environnementale. Lors de l’élaboration des programmes éducatifs, il est donc important d’inclure des enseignants pour veiller à ce que les visions et besoins locaux soient considérés, ce qui donnera plus de chances aux dits programmes de prendre du sens et de servir leur dessein.

INTRODUCTION
ENVIRONMENTAL EDUCATION. Environmental education became globally recognized some 40 years ago (Palmer 2003) and today comprises all efforts that help individuals or societies to develop the necessary skills to enable informed decisions and actions to improve the environment. The objectives of environmental education were defined and refined during the international environmental workshop in Belgrade, Yugoslavia (Belgrade Charter 1975, UNESCO 1976) and the first international inter-governmental conference on environmental

education in Tbilisi, Georgia (Tbilisi Declaration 1977, UNESCO 1978). The objectives of environmental education are to help groups and individuals to develop (i) ‘awareness’ towards the environment and environmental problems, (ii) ‘knowledge’ and a basic understanding of the environment, its ecosystem functions and services, and linked problems, (iii) positive ‘attitudes’ and concern for the environment and the motivation for active participation of individuals and societies in environmental improvement and protection, (iv) ‘skills’ for identifying and solving environmental problems, and (v) ‘participation’, i.e., being actively involved in solving environmental problems (UNESCO 1976, UNESCO 1978).

Agenda 21 (the global action plan towards sustainable development adopted at the UN Conference on Environment and Development held in Rio de Janeiro, Brazil, in 1992) points out the crucial role of education for reaching sustainable development, declaring it to be “critical for achieving environmental and ethical awareness, values and attitudes, skills and behavior” (UNCED 1992: 320). People educated in this way will be capable to understand environmental and development issues and to act accordingly, thus allowing public participation in decision-making and ensuring sustainable development in the long-run (ibid). The UNESCO states that “educators are one of the most important levers to realize educational change and to facilitate learning for sustainable development” (UNESCO 2013: 2).

ENVIRONMENTAL EDUCATION AND SUSTAINABLE DEVELOPMENT. The concept of sustainable development was first recognized in the World Conservation Strategy (IUCN 1980), and reached fame with the Brundtland Report “Our common future” seven years later where sustainable development was defined as “meeting the needs of the present without compromising the ability of future generations to meet their needs” (WCED 1987: 43). The Report applied a global view on the links between environmental and socio-economic issues, as well as future well-being for humanity, considering an economic, social and political perspective. It expressed human’s dependency on the environment as well as local, regional, national and global linkage and interdependency of ecology and economy (WCED 1987: 5). Education has been assigned a key role in achieving the global aim of sustainable development (IUCN 1980). The fourth international conference on environmental education, Tbilisiplus30 dealt with the arising question how to bridge the gap between environmental education and education for sustainable development and set a global agenda for the ‘UN Decade of Education for Sustainable Development’ for the period 2005 to 2014 (Combes 2005, Limmatainen 2013) in order to establish an essential contribution to human development.

While environmental education focusses on the amelioration of the environment with no close link to development, education for sustainable development is concerned about the human beings, linking environmental and developmental issues (Pavlova 2011). According to Agenda 21, “Education, including formal education, public awareness and training should be recognized as a process by which human beings and societies can reach their fullest potential. Education is critical for promoting sustainable development and improving the capacity of the people to address environment and development issues” (UNCED 1992: 320). There is, however, a discrepancy in the interpretation of the two paradigms of environmental education and education for sustainable development (McKeown and Hopkins 2003); some countries use these concepts interchangeably, while others see the first as part of the second, or vice versa (Pavlova 2011).

The UNESCO proposal for the Global Action Programme (follow-up for the ‘UN Decade of Education for Sustainable Development’ after 2014) applies the term ‘education for sustainable development’ for all activities that will promote such evolution, “(...) irrespective of whether they themselves use the term ESD or – depending on their history, cultural context or specific priority areas – environmental education, sustainability education, global education, development education, or other” (UNESCO 2013: 2).

THE MADAGASCAR CONTEXT. A growing challenge in many developing countries is the reconciliation of a continuously increasing demand for agricultural products while conserving biodiversity, maintaining ecological functions and providing critical ecosystem services to sustain local livelihoods (Harvey et al. 2008, Brussaard et al. 2010). Madagascar, despite having received considerable international conservation and development attention in the past decades (Horning 2008), is still one of the poorest countries (UNDP 2013) while facing continuous degradation of its natural environment and an ongoing loss of its unique biodiversity.

The Human Development Index (HDI), calculated by the United Nations Development Programme (UNDP), is an alternative measure to the better known Gross Domestic Product (GDP) to assess a country’s development state, which is measured by achievements in the dimensions of life expectancy, education, and available resources for living. Education is especially important as a stepping stone towards improved health; according to the UNDP, “a mother’s education is more important to her child’s survival than is household income or wealth” (UNDP 2013: 89). Madagascar with a HDI of 0.483 ranks 151 out of 187, figuring in the ‘low human development group’ together with many other African countries (UNDP 2013). It has globally one of the highest population growths rates (3 %) and one of the lowest median ages of 18.2. This is paralleled by an extremely high primary school dropout rate of 65.4 % (in comparison, total sub-Saharan Africa is at 37.8 %, countries from the ‘very high human development’ group oscillate around 3.8 %) leaving the majority of Madagascar’s population without any secondary or tertiary education. Mean years of schooling in Madagascar are at 5.2, opposed to 11.5 in countries with high HDI, but still better than in Sub-Saharan Africa with 4.7 (ibid).

Madagascar is at great risk of increasing vulnerability and degradation due to overexploitation and climate change (Hannah et al. 2008, Shepherd et al. 2013); the 2030s-projections of vulnerability to climatic extremes and disasters even put Madagascar into the globally highest risk group due to its increasing poverty (Shepherd et al. 2013). Education is crucial to acquire further competences needed to deal with threats in the future (Muttarak and Lutz 2014). This begs the question whether the current school system is capable to shoulder this responsibility?

EDUCATION IN MADAGASCAR. Madagascar had one of the first Sub-Saharan African school systems during the Merina Kings and Queens period with formal schools mainly in the central highlands around Antananarivo, targeting the noble classes (androina) only (Antal and Ndrianjafy 2013). With the French colonialists the formal school system started to reach

more remote areas in Madagascar. The education system in Madagascar was modeled based on the French system: maternelle, collège, and lycée with the baccalauréat exam at the end, and option to continue at university level (Sharp 2002). The Malagasy school system continued to mimic the French one also after Madagascar's independence (1960) and lasted until 1972, marking the end of the First Republic under President Philibert Tsiranana (Randrianjara and Ellis 2009).

The period of ‘rebelling’ began in 1972 when a nationalist movement demanded the end of ‘neo-colonialism’, leading to the fall of the Tsiranana regime and the creation of a transitional government responsible for the introduction of the malgachisation of teaching (ibid). A socialist revolution led to the Second Republic under President Didier Ratsiraka, who adopted and furthered the malgachisation beyond the education system (Johnson 2006). Ratsiraka introduced the official Malagasy language, which was based on the Merina dialect from the central highlands. As a consequence, many non-Merina teachers speaking different dialects, and who had received all of their previous education and training in French, struggled to suddenly use exclusively the new official language (Sharp 2002). The promotion and propagation of new schools by the socialist regime led to a lack of well trained teachers, but also a lack of financial resources impeded the new government to target the country’s 11,000 fokontany, especially in more rural areas. Parents often had to collect money to contribute or pay the salaries of the teachers or to provide teaching equipment such as textbooks or furniture (Johnson 2006). The lack of Malagasy teaching textbooks forced many teachers to translate the French textbooks into Malagasy. Consequently, little Malagasy culture was actually taught in schools (Sharp 2002).

With the installment of the Third Republic in 1992 under President Albert Zafy, many policies were reversed again, and French was reinstalled to assure quality in teaching and education. According to Johnson (2006), however, the problem was now a lack of teachers being able to speak and teach in French, since many teachers serving under the First Republic had in the meantime been retired. Another recurring problem was the lack of French written textbooks. The Forth Republic of President Marc Ravalomanana was a period of ‘policy borrowing’ (cf. Johnson 2006) to improve the school system by looking at other countries’ systems. English as third official language was also introduced as third school language in primary schools. The Malagasy school system continued to mimic the French one also after Madagascar’s independence (1960) and lasted until 1972, marking the end of the First Republic under President Philibert Tsiranana (Randrianjara and Ellis 2009).

A case study done by Durrell has shown a positive correlation between education and environmental awareness (Andrianandrassana et al. 2005). The Madagascar Wildlife Conservation (MWC) found increased knowledge for environmental issues in school children after participation in the environmental education program (Dolins et al. 2010, Rendigs et al. In press). MWC has been running this program since 2006 and developed culturally and regionally adapted posters and comic books for the region to be used in public primary schools by trained teachers (Maminirina et al. 2006).

The goal of this study is to assess the state of environmental education in the Alaotra primary public schools. It is assumed that significant numbers of future resource users can be reached if environmental education is implemented on primary school level. Environmental education can strengthen conservation efforts such as maintaining ecosystem functions and biodiversity by contributing to improved awareness of and appreciation for the natural environment. Assessing the current situation is the first step in developing suitable and regionally adapted environmental education programs. Such education is hypothesized to advance sustainable development. This paper has two main objectives: (i) to understand the perceptions of ‘environment’ and ‘environmental education’ at primary schools at the teacher level, and (ii) to describe the school structure in terms of readiness for environmental education.

**METHODOLOGY**

A total of 18 primary schools around Lake Alaotra were selected based on the following criteria: (i) Public primary school; (ii) adjacency to the lake and remaining marshes; and (iii) accessibility, i.e., vicinity to Routes Nationales 3 and 44 (east and west coast of the lake, respectively).

Structured one-on-one interviews with 54 teachers (including 18 school directors) were conducted. Half of the interviewees were selected based on participant lists of former MWC trainings and the other half were randomly sampled teachers without such training. A standardized interview guide according to the Funnel approach (cf. Wittkowski 1994) has been developed in order to avoid a social desirability bias (Paulhus 1991). Interviewers using the Funnel approach start with broader
subjects and gradually narrow down their topics of interest, thereby masking the motivations of the interviewees from the interviewees. The Funnel approach is intended to reduce the tendency of interviewees to answer questions in a way they believe the researcher welcomes, instead of offering their own opinions (ibid). All interviews were audiotaped, transcribed and translated from Malagasy into French. Average interviews were 60 to 90 minutes. Prior informed consent was obtained regarding audiotaping ensuring the teachers’ anonymity. It was emphasized that there were no right or wrong answers but a range of different personal opinions. A pilot interview guide was tested with the interviewer, a Malagasy anthropologist, to ensure methodological adequacy and cultural sensitivity, profiting from his experience during former surveys in the region. The interview guide addressed four major topics with multiple sub-questions (cf. Supplementary Material for details): (i) general situation in the village, e.g., social environment; (ii) school environment; (iii) natural environment; (iv) teacher trainings. Major topics included structural conditions of the schools such as availability of material and trainings, environmental situation and problems in the region, as well as environmental education and possibilities of its implementation. After each interview, participants completed a short questionnaire, indicating biographical information and details on their personal education and career.

To allow for triangulation of results, the structured interviews were complemented by further applying a participatory problem analysis workshop, ARDI (Actors, Resources, Dynamics, Interactions; Etienne et al. 2011), focus groups, participant observations and archival research. ARDI is a methodology deployed to collectively analyze a problem. During this two-day workshop, 12 teachers (randomly selected from the 54 interviewees) addressed the problem that there is not enough material for (environmental) education, and determined involved actors, existing and needed resources, dynamics in the system, as well as interactions between its components. Additionally, 6 focus groups totaling 50 participants were conducted. The majority of the teachers were the same as for the interviews (with few replacements). These meetings followed a similar structure as the interviews, but permitted further discussion in greater detail of teaching approaches and other issues. The interviews had revealed some gaps that could be filled with the results from the workshop and meetings. Additional data to complement and verify the interviews was obtained from the group approaches.

Data analysis was supported by the commercially available software program MaxQDA 11 which uses data management techniques such as multiple levels of coding, memo creation and code segment search. Coding is the method by which text is classified, analyzed, and grouped into categories. These were developed, tested and adapted while considering objective, research questions, methodological approaches and resources.

RESULTS

PRIMARY SCHOOL SYSTEM. The two Alaotra CISCOs (Circonscription Scolaires) with 43 Chef ZAP (Zone Administrative et Pédagogique, the administrative districts) currently oversee a total of 702 primary schools; 540 EPPs (Ecole Primaire Publique, public schools) and 162 EPs (Ecole Privée, private schools). Over 3,300 teachers are responsible for the education of nearly 116,000 pupils between 7 and 15 years old (Maminirina et al. 2006, CISCO 2013). The CISCO Ambatondrazaka teaches students from first to fifth grade while pupils under the authority of CISCO Amanaparafarava are supposed to attend primary school until seventh grade (T7). However, T6 (6th grade) and T7 are realized in 61 out of 343 schools only (57 public and 4 private schools) resulting in 17.8 % of the schools implementing this new model of having seven grades in primary school since 2009.

There are three employment types at EPPs: i) Fonctionnaires: 930 (37 %) of the present teachers were recruited and are paid directly by the Ministry of National Education; ii) ENFs: 969 (38 %) are community recruited teachers; the ENF subventionné (Enseignant FRAM) are paid half by the Ministry of National Education, and by the pupils’ parents, respectively; iii) ENF non-subventionné: 643 (25 %) have to be financed by the parents alone.

The 18 sampled schools have an average class size of 49 pupils with a minimum of 18 and a maximum of 92 children per class. School sizes ranged from 5 to 23 classes with 4 to 24 teachers, respectively. Of the 54 interviewees, 74 % were women and 26 % men, reflecting the fact that the majority of the Alaotra EPPs’ teachers are women. The retirement age for teachers is at 60 years. The sample size shows that more than half of the teachers are close to retirement (53 %). Almost all teachers have attended secondary school, but only 9 % hold a university degree. Out of the 54 teachers, 65 % are Fonctionnaires, 17 % are ENF subventionné, and 18 % are ENF non-subventionné.

The CISCO’s responsibility is to implement the school program that the Ministry of National Education delivers via the DREN (Direction Régionale de l’Education Nationale, regional authority for education). The main objective is a continual amelioration of results, i.e., the increase of successful exams passed by the school children. The Chefs ZAP assist the CISCO in the delivery of the school curriculum’s content by organizing training sessions to transmit instructions and methodological modifications to the directors and teachers of the EPPs.

According to the teachers, teaching subjects are received in irregular intervals (e.g., the CISCO organized trainings every trimester or every three months). Each month there is a Journée Pédagogique (one day teacher training) and once a week a Conseil de Maîtres (teacher’s meeting) during which the teachers have the opportunity to exchange with their school directors and amongst peers. The Chef ZAP as instructor can be supported by the CISCO’s Equipe Pédagogique as there are the Adjoint Pédagogique, the Conseillers Pédagogiques and the Chef CISCO. The CISCO is also responsible for the follow-up and monitoring of the teachers. These suivis are mainly conducted by the Chefs ZAP and serve as control measures to ensure the curriculum-relevant topics have been transmitted properly during the CISCO trainings, but also to assess the teachers’ ability to implement the provided subject contents.

SCHOOL CURRICULUM AND TEACHING METHODS.

One school year in Madagascar lasts nine months, i.e., from October to July. Generally, there is one teacher for each class, teaching all school subjects in the respective level (T1–T5/T7). A lesson takes 30 minutes while the teaching approach consists of consecutive stages which must be completed in order. The revision of the previous lesson is followed by an introduction and préacquis, i.e., children will recall what they know already about a certain topic. The next steps are giving the title of the
To execute their lessons, several approaches are available as teachers stated in the ARDI workshop: banking education (sensu Freire 1970, Dewey 2004) where the teacher presents the content to the pupils without discussion or any other interaction; the active and participatory method that are the most efficient ones for teaching, allowing pupils for example to manipulate material during experiments; different strategies such as group work and individual work, encouraging the pupils to play games or using little songs and rhymes to transmit the lesson’s content. These methods and strategies are supplemented by approaches (démarches) and procedures (procédés) from the Ministry of National Education and NGOs. According to the teachers interviewed, the teaching methodologies are changing frequently with the mandatory application of new approaches promoted by the CISCO: APC (Approche Par la Compétence), APS (Approche Par la Situation), MITAFA (Miara-mamolavoly ny Tanana ho Fahalalàna), doing experiments with the pupils to understand science; introduced by DEFI, a French NGO. There is a trend to move away from the banking education towards more group and participatory work which is for example encouraged in the APC context. In order to comply with the new directives despite a shortage of material, the teachers oftentimes are forced to develop teaching material on their own. However, since teachers are required to follow the school program, there is often insufficient time available for implementation of these non-traditional methods (e.g., going to the market to introduce mathematical problems in an interesting way).

The main school subjects are mathematics, Malagasy, earth and life science (SVT: Science de la Vie et de la Terre), geography, French, social studies (TSM which includes FFOM/ éducation civique and history); complemented by music, art, sports, recitation (i.e., repeating something aloud from memory, e.g., recitation of traditional poems) and reading. The teacher’s ranking of these school subjects revealed no common agreement on their practical importance for students later in life. There is, however, a trend showing reading to be the most important skill for adult life, followed by Malagasy, writing and mathematics; the non-school subject household is ranked on second place while environmental education figures comparatively low (Figure 1).

TEACHER’S UNDERSTANDING OF ENVIRONMENTAL EDUCATION. Teachers’ understanding of education in general is described mainly as “transmission of knowledge”. Several teachers added that education is “learning on the intellectual, physical, and spiritual level” while others described it as learning how to act as a “good citizen”, i.e. showing a “good behavior in society”. To better understand what exactly environmental education means to the local teachers, we asked this question in the face-to-face interviews, as well as in the ARDI workshop and focus groups. During these group meetings, the following definition of environmental education has been compiled: it is the “transmission of knowledge about the environment”, thus “learning about everything that belongs to the environment, about existing environmental problems and their possible solutions”, and about the “protection of the environment”. The teachers stated that it is important to know who the actors are (who have destructive impact on the environment) to be able to “become a responsible citizen”. While teaching environmental education, knowledge on “everything that surrounds us”, “the whole that is visible and invisible” has been transmitted. According to them, both, natural environment (e.g., water, forest, including humans) and anthropogenic environment (e.g., houses, roads) are addressed.

During the one-on-one interviews, simpler definitions of environmental education were listed compared to the group meetings, mainly encompassing what the environment entails and defining environmental education as “transmission of knowledge about these components”. Some teachers however also included the conservation aspect: environmental education is “teaching the pupils about the components of the environment and its importance. How can it be conserved? Who is responsible for its destruction? What are the consequences of this destruction?” Another interviewee stated that “environmental education is teaching people what the environment constitutes, its state or condition and finally its conservation”.

Teachers state that environmental education is already taught in the current school system even if no specific school subject exists for this. In their opinion, best suitable for the integration of the environmental topics are the school subjects SVT (Science de la Vie et de la Terre), FFOM and geography, but also Malagasy, French, history and even mathematics offer such possibility to some degree.

Building on this background, teachers’ opinions on the importance of environmental education compared to school and other non-school subjects varied: though environmental education ranked amongst the least important topics on average (Figure 1), personal opinions were quite diverse. Sixteen percent declared environmental education to be the most important topic, 12 % ranked it on 2nd, 18 % on 3rd and 4 % on 4th and 12 % on 5th rank. The remaining 40 % were distributed on ranks 6 to 11. None of the interviewees ranked it the least important topic for a primary school. In terms of a possible implementation of environmental education, 100 % of the interviewees said that it already is included in the current curriculum, i.e., environmental education appears in many of the topics they are teaching while several book chapters are dealing with the environment. Geography deals with environmental destruction by addressing bush fires and tavy (slash and burn agriculture). FFOM (Fana-beazana sy Famolavolana Maha-Olomendrika, i.e., education
with the aim to make the children become an adult person with good manners) also deals with ‘the environment’ where they introduce environmental education by addressing ‘all questions concerning the health as for example personal hygiene’. When they present possible consequences of using river water, “the environment is already introduced”. This example suggests that some teachers believe environmental education is sufficiently taught as soon as the natural or social environment is barely mentioned. Teachers state that other book chapters are explaining ‘What is the environment?’ or treat the topic ‘How to avoid erosion’ or ‘The protection of the environment’, herein focusing on the protection of plants and animals.

The teachers are aware of many kinds of environmental problems in and around their villages. These can be grouped into the three categories ‘ecosystem’, ‘humans’, and ‘agriculture’ (Figure 2). The ecosystem perspective entails destructive human practices and their consequences on the natural environment. The social or human perspective mainly focusses on problems in the village that are related to the low development state, and the agricultural perspective comprises causes of management practices and their consequences on the agricultural output. When describing problems of the natural environment, the teachers oftentimes just briefly mention the environmental issue and then focus on the social impact resulting from it.

When answering the question about regional environmental problems, one third of the interviewees mentioned poverty as a cause for environmental destruction and one fifth tried to explain people’s behavior with their mentality or mindset, in particular referring to people’s laziness and jealousy: “They know that they shouldn’t burn the marshland, but when they see the advantages and benefits of the persons who protect the environment here, they ask themselves why this benefit is not shared but reserved to and kept by one person. So they quarrel in periods like now [political instable times with no work positions] and in periods like now [political instable times with no work positions] they continue to burn the marshland”. Speaking about mentality, one third of respondents complained that people do not plant trees or do reforestation but also address the problem that “someone burns them [the planted trees] all the time”. Teachers declared fire to be the most threatening problem for an intact environment when showing them ten different photographs with potential environmental problems being present at the lake to date. These photos were chosen according to what had been encountered during the first few weeks on the ground, either by sight or by reports from residents. Almost all interviewees also identified charcoal and erosion to be important environmental pressures (98 and 96 %, respectively), as well as crayfish (92 %). Inundation was judged a potential environmental problem by 77 % of the interviewees, while the invasive fish species snakehead and pesticides were identified by 58 % and 40 %, respectively. Only 25 % declared (marsh-penetrating) zebu to be potentially problematic; 6 % listed the invasive plant water hyacinth; rice fields were not listed by any of the teachers (cf. Supplementary Material).

FIGURE 2. Listing regional environmental problems. The teachers specified environmental problems as perceived by them (“Please describe the environmental situation in your community. Are there environmental problems? Which environmental problems do exist?”). The various answers were grouped into the three main categories ‘ecosystem’, ‘humans’, and ‘agriculture’ (problems that affect directly the agricultural production) with the above listed sub-categories. X-axis is the percentage of interviewees (n=48) who mentioned the respective issue listed on y-axis.

DISCUSSION

LANGUAGE BARRIER. Since many of the Alaotra teachers are not confident with French or speak only little to conduct extensive discussions, all data sampling had to be done in Malagasy. Interestingly, many of these teachers are from the generation of the malgachisation and hence did not have the opportunity to learn French. To reduce the risk of missing out on details, i.e., getting lost in translation, different approaches for data sampling were used allowing for triangulation of the results. Additionally, random translations have been cross-checked by the interviewer to ensure quality. Though even with a seemingly small data set (n = 54 out of over 3,300 teachers of public primary schools) we can be confident that the data set is representative, since there were many agreements in terms of responses.

Another language barrier is present in the school system itself. Today, Malagasy primary school classes are bilingual (Malagasy and French). In the first two grades, pupils are taught in Malagasy, the third grade allows theoretically a bilingual transition to 4th and 5th grade where lessons are or at least should, according to the curriculum, be held in French. The question remains, however, to what extent this is or can be realized by the teachers that were educated during the malgachisation. Various publications declare the teaching language a key factor for learning (Brock-Utne 2000, Heugh 2000, Benson 2004, Abadzi 2006) and state the importance to teach in the mother tongue. Language as “basic tool for thought, communication, reasoning, and making sense of a rapidly changing world” (Arnold 2004: 3) can even serve for predicting later abilities and school success (Hart and Risley 1995, Shonkoff and Phillips 2000). In Madagascar, however, exams are held in French from the third grade on which poses a great language barrier to learning and succeeding at school.

LACK OF TRAINED TEACHERS. In the Alaotra region, the primary public schools are facing an uncertain near future due to an increasing lack of professionally trained teachers. A significant body of aging teaching staff is currently close to retirement and teachers are complaining that since 2009 there is no more recruitment of teachers paid by the state (fonctionnaires) and thus more ENFs (community-recruited teachers) are hired for less payment. Fonctionnaires normally obtain trainings for two years at the École Normale before they are recruited by the Ministry of National Education, whereas the ENFs are selected via application by the CISCO without necessarily having such a considerable education. This could potentially contribute to a deterioration of teachers’ educational levels in the region.
Our data sample includes 65% fonctionnaires opposed to 37% in reality. This might result in a slightly different picture regarding teacher’s educational levels as well as knowledge and understanding on certain topics. If few well-trained teachers are recruited, this inevitably will leave a void and the overall educational quality level in the first grades will decrease. It is well-known, however that quality teaching is especially crucial in the first grades (Bruns et al. 2003, Abadzi 2006) and that attitude and behavior are mainly developed based on experiences in childhood (e.g., Kidd and Kidd 1989, McDuff and Jacobson 2000, Jacobsen et al. 2006). Sobel (1997) admonishes not to impose ecological problems on children before a certain age to avoid the feelings of fear and disempowerment (‘ecophobia’). He suggests age-appropriate environmental education contents for developing the necessary emotional connectedness that will later allow them to deal with the complex ecological issues. Such age-appropriate education, however, requires accordingly trained teachers.

Ongoing political changes and irregular trainings pose on the one hand insecurity and require (methodological) adaptation by the teachers, but also give them the impression that their “expertise is questioned”. On the other hand, the principle formation de formateurs (cascade training: the Chefs ZAP will train directors and teachers on the ground after having received trainings themselves) can offer an effective approach for introducing new methods and the changing requests by the Ministry of National Education keep the educators flexible and open for new teaching approaches. Since 2012 (start of the AMBio research project, Alaotra Marshland Biodiversity), the Chef CISCO in Aamparafaravola and lately the Chef DREN in Ambatondrazaka have been replaced, and further changes are likely to follow. Such instability might be one reason amongst others why plans by the government to restructure and improve the school system, and even to include Malagasy biodiversity into teaching, have been on hold (Dolins et al. 2010). Even if the Malagasy curriculum addresses some environmental topics (cf. Ormsby 2008) there is a lack of site-specific content.

In the past decades, NGOs have been filling these gaps by providing educational material and proposing new teaching approaches (e.g., Waeder 2006, Maminirina et al. 2006, Dolins et al. 2010). However, the provision of material alone might not be sufficient when teachers do not know how to use the material (cf. Dolins et al. 2010) or if they lack understanding of the topic or the motivation to teach it. Developing locally adapted tools and training teachers in how to use them might increase the chance of meaningful use of such educational material in the classroom. The integration of new material should be endorsed by the CISCOs, an approach generally taken (cf. Pidgeon 1996) that are still common today and consumed locally, presenting an environmental problem (as assumed by a western audience). However, in the Alaotra region none of the interviewed teachers did refer, for example, to ancestors as part of the environmental context. This assumption is illustrated by the following example. Many teachers mentioned ‘polluted air’ as environmental problem. French textbooks that are still in use (pers. obs.) are dealing for example with the negative impacts of factories on air quality and consequences for human health. There is no such air pollution in the Alaotra region, but teachers adopt this textbook content on their regional reality: “the environment is also affected because there are no toilets; people defecate everywhere and the air is thus polluted”. Polluted air is also oftentimes mentioned in the context of waste dispersal and the lack of garbage disposals.

When the teachers ranked the different ‘environmental problems’ during the interviews, a congruency of western and regional perceptions appeared, for example regarding fire and charcoal of being main threats in the region. On the other hand, there was often hesitation or confusion whether, for example, the invasive fish species Channa maculata is representing an environmental problem (as assumed by a western perspective because it feeds on endemic fish and bird species (Andrianandrasana et al. 2005) or not. This species was chosen as representative for introduced fish species at Lake Alaotra (cf. Pidgeon 1996) that are still common today and consumed regularly. Many teachers mentioned that the fibata (vernacular name for C. maculata) eats little fish or even stated that it is the enemy of the fish stock in general. But in an environment where main nutrition and lack of protein are wide-spread, some teachers still decided not to put C. maculata as environmental problem despite knowing its ecological impacts. This fish thus represents a good example for a trade-off situation between negative environmental impacts versus an improved social situation. The question arises how committed and supportive the teachers can or will practice environmental education if their own ‘Lebenswelt’ (this translates as ‘human-life world’),
cf. De Laguna 1960) is not reflected in the teaching material and content? Local realities need to be taken into account to increase probability of acceptance and success of environmental education programs.

Following the UN, teachers are seen as crucial in delivering the sustainability message. At first glance, the teachers’ understanding on environmental education seems to be congruent with the international definitions (cf. UNESCO 1976). The teachers define it as the "transmission of all knowledge that is related to the environment (...)" with examples for environment such as forests, the air, stones, roads, and houses. In contrast, the UN concept of environmental education incorporates much more than the local perspective which represents only the first step, the knowledge transfer, of the international definition. Though knowledge is crucial in achieving higher cognitive levels such as understanding, awareness and sensitivity, attitudes and motivation, and skills for participation and action, pure knowledge transfer is clearly not sufficient as teaching objective.

According to the teachers, environmental education already appears in many of the topics they are currently teaching, and several text book chapters are dealing with the environment. However, as some of the following examples show there is a disparity of what the authors understand of environmental education and what the teachers think in this regard. For example, one teacher stated that she included environmental education by giving an arithmetic problem where the children had to calculate the benefit of 20 planted shoots of manioc. Another teacher claimed teaching about health centers to be environmental education, while another stated that discussing the benefits of trees on the hill slopes around Lake Alaotra constitutes environmental education.

During the interviews, when the Alaotra teachers listed environmental problems, the focus revolved mainly around social and health related topics (‘humans’). The teachers revealed detailed descriptions and understanding of problems when they talked about social and economic misfits using oftentimes compelling examples. Fewer details were touched on when talking about the natural environment, by barely naming a problem or briefly listing a sequence of several ecosystem-related issues, to end in many cases again with a social-centric environmental problem: “the bush fire causes soil loss and hence the canals here get clogged by the accumulation of mud which are brought by the waters and the streets get flooded”, or, “even the well (...) is not very sanitary because it is not covered and when the rain is arriving, the drain water pours into the well, together with the waste from the surroundings”. This emphasis on social impacts, even when ostensibly speaking about natural environments, matters locally and needs to be addressed when drafting environmental education programs. During some of the interviews, the impression occurred that the teachers were citing facts without deeper understanding of interrelationships or reasons. Many of the Alaotra teachers are from the generation of the malgachisation and have been indoctrinated with recitation teaching by the socialist regime. This causes unpredictable consequences for the next generations as these educators did not learn how to think critically but to learn by heart and to repeat slogans only.

As long as the Alaotra population suffers from deficient hygiene and health issues there will be little sympathy for ecosystem problems, and relationships between deteriorating ecosystem services and health or development might remain misunderstood. A central question remains how the different value systems of external western providers of environmental education (such as NGOs, cf. Rendigs et al. in press) and local teaching staff and communities can be married to achieve development in all environmental aspects in combination with conservation success. This is where environmental education can act as leverage, emphasizing the linkages between a healthy environment and its services, but also by serving the local needs by introducing for example concepts such as PHE (People, Health, and Environment; cf. Robson and Rakotozafy In press) for a successful model in Madagascar.

FROM TEACHER-CENTERED LEARNING TO LEARNER-CENTERED APPROACH. As Kollmus and Agyeman (2002) state, there is no apparent, direct correlation between knowledge and pro-environmental behavior. Having in mind that action competence may be the one main goal of environmental education, Jensen (2002) adds that a clear distinction should be drawn between behavioral change and action. Behavioral change is oftentimes directed by others, while action “should be directed at solving a problem and it should be decided upon by those preparing to carry out the action” (Jensen 2002: 326), direct or indirect, individually or collectively. How these obvious gaps between environmental knowledge and attitude change towards positive environmental actions may be bridged is still open to debate. It is well known that knowledge about and positive attitudes towards the environment are necessary prerequisites but in themselves are not strong enough to lead to action (Schultz et al., 2011, Heberlein 2012). An environmental education program aimed at changing people’s behavior should therefore steer away from teacher-centered learning (banking education). It needs a learner-centered approach that is connected to the scholar’s every-day life and has a real issues orientation, and is in its nature participatory and allows the learning process to be driven by the learners. It should integrate new teaching methods like outdoor activities, participative inquiry, group activities and discussions or action learning on real-life problems. This approach targets a broad set of scholars’ competencies, thereby facilitating systemic and critical thinking, reflection and future orientated thinking. This strengthens the competencies of learners for shaping their future in a positive way (consider Palmer 2003, Tilbury 2007, Cotton and Winter 2010, de Haan 2010, for an in-depth discussion on appropriate teaching methods). Furthermore, a culture-specific approach to environmental education taking into account local values and belief systems is also needed to address and ensure environmental behavior via education (Boeve-de Pauw and Van Petegem 2011).

The concept of the Gestaltungskompetenz (cf. de Haan 2006, and references therein) promotes a learning to invoke change (in for example ecological, economic or social behavior) through a combination of skills acquisition and competencies (i.e., to build on children’s every-day experiences) that goes beyond the pure accumulation of ‘inert-knowledge’ (sensu Renkl et al., 1996). Such knowledge-based or banking education is one of the main challenges in Madagascar’s school system. Not surprisingly, teachers judge the school subjects reading, Malagasy, writing, and mathematics as likely most important to be successful in after school life, being congruent with the set
of principles the Ministry of National Education stated for their school children. When leaving the primary schools in Madagascar they are expected to master (i) academic achievements such as skills in reading and writing, arithmetic, and problem solving (e.g., Bloom’s taxonomy: comprehension, application, analysis, synthesis and evaluation), (ii) social skills (attitudinal modernity, interpersonal effectiveness, community involvement), and (iii) economic success (earnings and productivity) (Heneveld and Craig 1996). The non-school subject household being ranked on second place by the Alaotra teachers correspondingly represents the social perspective.

The social environment is in teachers’ perceptions higher prioritized than the natural environment. Teachers are exposed on a daily basis to social problems which are consequences of the urban environment and carried by the children into the class rooms. For example, many students come from impoverished households, are malnourished, and have poor hygiene. It has been shown that socioeconomic status globally plays a crucial role in children’s development (Brooks-Gunn and Duncan 1997, Bradley and Corwyn 2002), and that such low status negatively affects behavioral and cognitive development in children (Gran- tham-McGregor et al. 2007). This results in poor performance which is reflected in the higher numbers of repeaters, or an increase in the drop-out rate (Arnold et al. 2007). Apart from this, it is well known that the experiences in early childhood shape the later learning processes; physical, cognitive, and emotional development of children are best supported by various and rich) natural settings, i.e., children have to experience nature themselves to achieve a holistic learning (cf. Rivkin 1995). Following a more proactive and interactive school approach by visiting, for example, the market or the marshes could already act as a stimulant in this direction. Although being envisioned by the school authorities, the realization of the approach remains a challenge due to lack of resources, time and motivation.

Even if the structure of the school system provides opportunities to address environmental education or education for sustainable development, environmental education as defined by the United Nations (UN) is to date implemented in the Alaotra region only on a basic level. Potential drivers and barriers of such implementation remain to be identified. Further research in the next two years thus will focus on barriers that are opposed to the implementation of environmental education into the school curriculum and drivers that will facilitate such implementation in the Alaotra region. Addressing the questions on what potential drivers represent, and how they could be used to tackle potential barriers will help to develop material that is adapted to the regional circumstances and learning environment. Including sustainability issues into the curriculum can be a challenge and should aim for addressing locally relevant terms and appropriate solutions rather than frightening the audience (children as teachers alike) with global problems, which are not understandable, likely irrelevant, let alone solvable on local scale and conditions (Tilbury et al. 2002).

CONCLUSIONS

The school system in Madagascar has a hierarchic structure, and changes are commonly dictated from the Ministry of National Education or DREN and CISCO. It is thus crucial to involve the higher levels of the school system when introducing environmental education, not only the schools themselves. The DREN and CISCOs are the official government entities for the realization of teacher trainings, and are crucial partners in the delivery and implementation of such new tools.

As the primary schools are the sole formal education for a majority of rural children, teachers could act as promoter of education that will allow pupil’s to face their future by furthering critical thinking. Teachers are shouldered with this responsibility. It is therefore important to overcome the banking education and to proceed towards a more participative and interactive learning, with teachers needing to be trained by the respective school authorities accordingly. Overcoming the impacts of malgachisation however, might still require some time and effort. The regional educators cannot be used only as instruments for implementation, but must be involved during the creation and development of educational tools or programs. It is assumed that this will increase teacher’s creativity, motivation and initiative in their teaching process. Including teachers in the tool development process will provide them with new techniques, new approaches, and especially increase confidence to address new topics or to try out new ways themselves.

When drafting environmental education programs, the population’s needs, concerns, and local value systems need to be taken into account. Consequently, a participatory approach needs to be chosen when drafting such programs. Given the anthropogenic view and emphasis on social values revealed by the interviews, the Alaotra schools and teachers might be better served with education for sustainable development rather than environmental education only. Following the principles of mutual respect, empathy and understanding will result in educational and development programs which can meet the expectations of all involved parties and are more likely to be continued even if projects or other external input such as funding are coming to an end.

ACKNOWLEDGEMENTS

The DREN, CISCOs, Chef ZAP, directors and teachers in the Alaotra region are acknowledged for supporting our research and for participating in our study. We thank Durrell and Madagascar Wildlife Conservation for their collaboration and the support on the ground. A special thanks goes to Antje Rendigs (MWC) for her continuous support, motivation, feedback and for sharing her experience in the region. Dr. Nils Benit provided valuable insights during the design of this study. Our acknowledgements are extended to the translators of the interviews and group discussions. Thanks to the Stifterverband für die deutsche Wissenschaft for financial support of the AMBio project, and to MCD’s anonymous reviewers and the editors for their comments on a previous version of this manuscript.
